Country Power Market Brief: Djibouti

Background

Djibouti’s government is strongly committed to increase electrification rates and diversify its energy mix. The country is endowed with high renewable energy potential (from solar, wind and geothermal) for on-grid and off-grid applications that, if properly developed, can contribute to improve its energy security, lower the tariffs, increase electrification rates and reliability in the supply.

Djibouti has low electrification rates, suffers from regular blackouts and high dependency on energy imports; and has one of the highest tariffs in the world. Meanwhile, the country’s power demand is growing fast as a consequence of its economic growth.

The present market brief was prepared in the context of the Africa-EU Energy Partnership Business Dialogue organised during the 29-30 May 2013 in Djibouti Ville with the main purpose to inform participants on the country’s power sector potential with a view to support dialogue between non-state and public actors.

Distances and routes are approximations. The power lines follow the roads appearing on this map. Tadjoura and Obock have isolated power networks.

2 Sources: AF Mercados, German Chamber of Commerce and the Centre d’Etudes et de Recherche de Djibouti.
Demand

In 2011, the total electricity demand represented 421.73 GWh distributed in three different systems, the main grid and two isolated networks. Djibouti’s demand is characterised by its fast growth levels. Power demand for the main grid is expected to grow by 70-75% in the period 2011-2035, while demand for the isolated networks of Tadjoura and Obock is expected to increase by 62.5% and 49.5% respectively during 2011-2035.

Supply

In 2011, total power supply represented 395.7 GWh. Production levels have been growing at an estimated annual rate of 5.7% over the last 40 years, but more slowly than demand. As a consequence of random and scheduled power cuts, an estimated 8.73 GWh of demand for the main grid could not be served in 2011. In 2011, the country’s total installed capacity equalled to 125.96 MW fully generated using diesel gensets distributed in four different generation plants.

The current network scheme is based on a 63 KV backbone, fed by Djibouti Ville generation units (Boulaos and Marabout) and the 230 KV Ethiopian interconnector. Isolated systems’ grids are based on lower voltage distribution networks. In 2011, grid losses represented about 16% of the electricity produced due to the poor state of the grid and illegal connections.

Djibouti decreased its power production by 37.64% over the 2010-2011 period as a result of the commissioning of Ethiopia’s interconnector which also allowed for a reduction in the non-served interconnected demand. Out of the total power supply, 154.97 GWh were imported from Ethiopia. Power imports from Ethiopia are regulated by a bilateral contract establishing a maximum energy trading of 243 GWh per year over the period 2012-2015 and up to 70% of the Djiboutian load up to 2019. It has set a very attractive tariff that varies between 6-7 USD cent/kWh.

Power production is largely based on thermal power plants, while, at the same time, Djibouti has no proven oil resources. As a result, its energy self-sufficiency levels are low (32%, IRENA, 2009) and its tariffs (USD 30 cent/kWh) remain amongst the highest in the world. In spite of this, the financial situation of Electricité de Djibouti (EDD), the state-owned and vertically integrated utility, continues deteriorating. Fuel subsidies represent a heavy burden for the State, up to 1.5% of its GDP (IMF, 2012).

As a result of the high tariffs and unreliable power supply, the private sector (e.g. Freeport of Djibouti) has developed its own means to produce electricity, but it is not allowed to sell excess power to the grid. The public sector remains the biggest consumer of electricity (40%) in Djibouti.

Policy targets and reforms

The Government of Djibouti has planned to increase its electrification rates up to 60% by 2015 and is strongly committed to support the development of the renewable energy sector. As a matter of fact, the increase in the share of renewable energies in the country’s energy mix has been identified as a key objective of its energy policy as well as of its Visions 2020 and 2035. In both cases, a target of 87-100% share of renewables in the energy mix has been set.

The authorities also aim to (i) improve the efficiency and financial performance of the electricity utility; (ii) refurbish and extend the power grid; (iii) and diversify power supply sources through exploration of renewable energy potential and the creation of interconnections (REEGLE).

As regards rural electrification, the government has set a solar development plan with the following targets: (i) equipping 70 rural boreholes and 100 other wells with solar pumps, (ii) equipping all rural health centres and 100 rural schools with solar arrays, (iii) increasing rural electrification up to 30% by 2017 with the installation of solar PV systems in 5,000 households (REEGLE).
Although the completion of the initial construction phase of the plant (50 MW) has been planned for 2013-2014, AF Mercados estimates that the earliest date for commissioning will be 2020.

Regarding wind, Djibouti’s Government has carried out feasibility studies in 14 sites, of which most of them have revealed average wind speeds above 5 metre per second (m/s). Ghoubet, Gali Maaba and Day gave results close to 9 m/s. According to AF Mercados, the site of Ghoubet remains the most interesting. The construction of a 20 MW wind park in Ghoubet is being considered by the European Commission for the provision of power supply to seawater desalination. China has also signed an agreement with the Djiboutian government to develop the wind resources in Ghoubet. Nonetheless, being located close to Lake Abbec, the Ghoubet project faces serious challenges due its remoteness. If the geothermal plant of the Lake Abbec is built, both projects could share the same interconnection line. Other possible locations such as Ali Sabieh, Bada Wein, Egralyta and Djibouti Ville have been identified to host wind farms with a capacity above 5 MW. Day, Hol-Hol and Yoboki have been identified to host wind farms with a capacity below 1 MW. The previously mentioned World Bank (WB) support programme also includes a small wind component for isolated areas.

Irradiation levels in Djibouti have been studied since the 1980s proving high potential all over the country (5-6.5 kWh/m2). According to the Centre des Etudes et la Recherche de Djibouti (CERD), the South-West is the region that enjoys the highest irradiation levels, particularly Dikhil. The Government plans to build a manufacturing facility of PV modules, and two grid-connected PV plants near Djibouti Ville, one of 10 MW (expandable to 25 MW) and another of 20 MW. The construction of a solar thermal plant with a 10 MW capacity is also being studied. The Agence Djiboutienne de Développement Social (ADDS) is currently developing an off-grid solar project aimed at achieving the targets set by the Solar Development Programme. The mentioned World Bank programme includes a feasibility study for solar rural electrification. Although not yet studied, hybridisation of the thermal plants of Tadjoura and Obock isolated systems could also be evaluated.
